```

Data Processing and Obstacles

- Data in Weather API was nested in a way that made populating tables in 3rd normal form difficult
 - Used a cross join lateral statement to populate the station table
- Joined on pulled at and Station ID
 - Incidents had their own coordinates
 - Calculated distance to nearest station
 - Iterated through stations and created a new column in incidents for nearest station

Our API

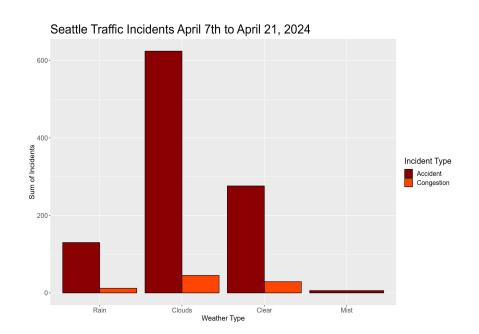

- Endpoints:
 - https://pikegomezapi-production.up.railway.app/cityweather
 - https://pikegomezapi-production.up.railway.app/portland
 - https://pikegomezapi-production.up.railway.app/seattle
- Outputs:
 - Weather Report at the stations within the city:
 - Temperature
 - Weather at the time
 - Count of Accidents
 - Count of Congestion Incidents

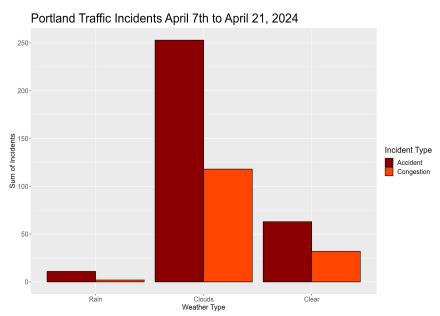

Does rain cause more accidents?

Hypothesis: Yes

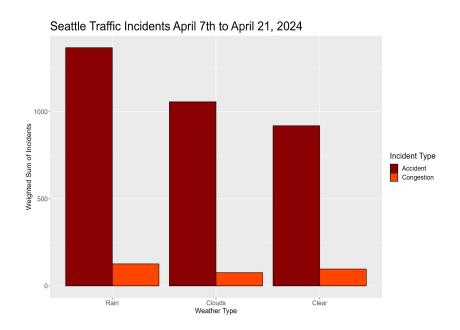

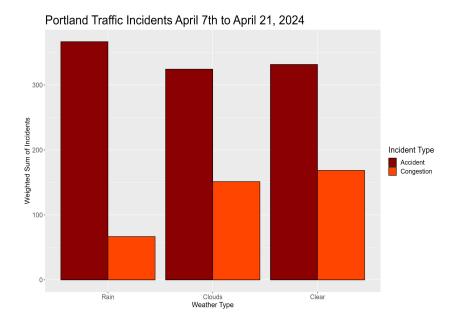

EDA: Sum of Incidents

Results: Weighted Analysis

Conclusions, Limitations, and Further Questions

- It appears that rainy weather does correlate with more accidents
- Two weeks is a small sample size especially when only pulling every 4 hours
- Cloudy was by far the most common weather type
- Timing of pulls doesn't exactly align with time of traffic incidents
- With more data, volume of rainfall could be taken into account
- Looking at cities where rain is less common could be interesting
- Set up more complicated API endpoints
